某软件charles抓包分析发现跟商品相关的请求头里都带了一个anti-token的字段且每次都不一样,那么下面的操作就从分析anti-token开始了。

1.jadx反编译直接搜索

选中跟http相关的类对这个方法进行打印堆栈。

结合堆栈方法调用的情况找到具体anti-token是由拦截器类f.a方法调用的,在http.a.c()方法中生成并且http.p.e()方法中加入请求头。

在http.a.c()方法中有个一个判断条件如果为true则走d.a().e()方法生成anti-token。

如果为false则走j()方法生成anti-token。

hook这个i()方法返回值可知获取商品详情接口返回值为false所以走的是j()方法进行计算 anti-token。

SecureNative.deviceInfo3()方法生成,传入的str为pdd生成的固定id 一个字符串。

根据hook_libart 得到info3()方法是在libodd_secure.so中,那么ida打开看看这个so包。

2.这部分我们采用unidbg+jnitrace+frida相结合的方式

unidb	a前期》	住备的代	说码这里就	不发了	'直接调	田汶イ	`info3	方法。
	M 177 / 47 / 1	<u>-</u>	U H J & 1// L		<u>—</u> 1×70.	/ 13 12 1		1140

这里提示调用gad()方法返回一个字符串那么frida hook这个方法拿到这个值 如下图 一个固定的字符串。

16位长度看着像AES的密钥。

继续补环境 这里简单补环境就不发了。

补完简单的环境代码后,再次运行报这个错误看错误应该是缺少文件,那么看看日志需要补那个文件。

继续运行,没有返回值报空指针。execve()函数执行的时候程序exit了这里我们返回对象本身。

execve()函数执行的时候程序exit了。

execve filename=/system/bin/sh, args=[sh, -c, cat /proc/sys/kernel/random/boot_id] 这个函数相当于查看 boot_id这个文件信息。

捋顺下逻辑应该就是先fork进程 然后在子进程中读取这个文件 然后把他写入pip中。

那么自定义syscallhandler后 再次运行成功拿到结果。

全部代码如下:

```
package pdd;
3 import com.github.unidbg.AndroidEmulator;
4 import com.github.unidbg.Emulator;
5 import com.github.unidbg.Module;
